

SYNTHETIC DEVELOPMENT DRAFT — unsent cover letter for author review; no signature.

Dear Journal Lens Editor,

We have prepared the Technical Note “Target composition can reverse an aggregate method comparison” for your measurement-comparison and diagnostic-methods readership. In the supplied synthetic comparison, opposite stratum estimates combine to +1.00 score under the equal sampled mixture and –0.20 under the target mixture of 0.8:0.2. The note's contribution is a transparent diagnostic of target composition, rather than a new causal or predictive method. It retains the g2 result and the target interval that crosses zero.

The package follows the supplied Lens policy v2 dated 2026-09-01: an anonymous editable manuscript below 2500 words, a separate title page, an editable figure/caption, supporting material, and a specific statement of restricted data and code access. The governing license prohibits redistribution of raw unit-level records and identifiers, while permitting local analysis, code and aggregate-result sharing.

This letter and package remain developmental drafts. Required author approval, funding, conflict and ethics declarations, contact information and any license-compatible controlled-access arrangement are pending. We do not assert submission exclusivity, approved authorship, approved ethics or unrestricted open raw data. No actual submission is being made or requested through this letter.

Corresponding author and signature: not supplied; author completion required.
