

S1. Units, mixtures and available evidence

The supplied version 2 evidence memo identifies eight independent paired units, four per stratum. A and B were measured on each same unit. Technical repetitions were averaged within unit/method after unit conversion. Repeat counts, conversion rules and unit records are not supplied. Independent-unit status is a fixture fact from the memo and method description, not a conclusion derived from a cited paper or verified from raw records.

The score difference is $A-B$; negative favors A because lower score is better. Target weights were fixed before measurement at $g1:g2 = 0.8:0.2$. The sample has four units in each stratum, giving equal sampled weights $0.5:0.5$.

Quantity	Mean $A-B$ (score)	Supplied 95% interval	Independent units
g1	-1.00	Not supplied	4 paired units
g2	+3.00	Not supplied	4 paired units
Equal sampled mixture (0.5/0.5)	+1.00	Not supplied	Same eight units
Target mixture (0.8/0.2)	-0.20	$[-0.60, 0.20]$	Same eight units

Arithmetic reconciliation: $0.5 \times (-1.00) + 0.5 \times 3.00 = +1.00$; $0.8 \times (-1.00) + 0.2 \times 3.00 = -0.20$. These are deterministic checks of supplied aggregates, not additional analyses on unit data. The two mixtures use the same units and are not two independent experiments.

The reported target interval is a 95% within-stratum paired-unit bootstrap percentile interval. The supplied method resamples paired units within each stratum and reapplies fixed target weights. Numerical source data, original analysis script, bootstrap realizations, seed, resample count and numerical software version are unavailable. Neither the bootstrap implementation nor its interval coverage has been replicated or independently validated in this task.

S2. Interpretation and access bounds

The evidence contains no treatment assignment, confounding measurement, equivalence margin, registered equivalence test or external validation. The g2 point estimate opposes an advantage for A. The target interval includes zero and both signs; this does not prove equivalence or exact absence of a difference. The comparison is a diagnostic of mixture dependence.

The fixture license permits local analysis, code and aggregate-result sharing but forbids redistribution of unit-level identifiers and raw unit-level records. Those records are not included. Any access proposal must be assessed by the responsible data holder against the governing license; no contact or approved access arrangement is supplied. Aggregate CSV and editable display code are included locally. They cannot reconstruct unit records or reproduce the original bootstrap.

S3. Citation scope

The two DOI identities in the supplied bibliography were checked against Crossref before this task, according to the fixture's source-availability record. That metadata check is distinct from semantic support. Efron (1979) is metadata-only here; neither its full text nor a verified supporting passage was obtained. Rosenbaum and Rubin (1983) are available here only through the fixture's paraphrase of the official abstract, concerning adjustment for observed covariates. Neither source verifies this fixture's independence, eliminates unmeasured confounding, or validates its empirical target interval. The misleading citations and both supporting reference entries have therefore been removed from the revised manuscript and retained in the separate citation audit; no substitute full-text evidence is invented.
